Quality Attribute Specification

- Architects are often told:
 - "My application must be fast/secure/scale"
- Far too imprecise to be any use at all
- Quality attributes (QAs) must be made precise/measurable for a given system design, e.g.
 - "It must be possible to scale the deployment from an initial 100 geographically dispersed user desktops to 10,000 without an increase in effort/cost for installation and configuration."

Quality Attribute Specification

- QA's must be concrete
- But what about testable?
 - Test scalability by installing system on 10K desktops?
- Often careful analysis of a proposed solution is all that is possible
- "It's all talk until the code runs"

Performance

- Many examples of poor performance in enterprise applications
- Performance requires a:
 - Metric of amount of work performed in unit time
 - Deadline that must be met
- Enterprise applications often have strict performance requirements, e.g.
 - 1000 transactions per second
 - 3 second average latency for a request

Performance - Throughput

- Measure of the amount of work an application must perform in unit time
 - Transactions per second
 - Messages per minute
- Is required throughput:
 - Average?
 - Peak?
- Many system have low average but high peak throughput requirements

Performance - Response Time

- measure of the latency an application exhibits in processing a request
- Usually measured in (milli)seconds
- Often an important metric for users
- Is required response time:
 - Guaranteed?
 - Average?
 - E.g. 95% of responses in sub-4 seconds, and all within 10 seconds

Performance - Deadlines

- 'something must be completed before some specified time'
 - Payroll system must complete by 2am so that electronic transfers can be sent to bank
 - Weekly accounting run must complete by 6am Monday so that figures are available to management
- Deadlines often associated with batch jobs in IT systems.

Something to watch for ...

- What is a
 - Transaction?
 - Message?
 - Request?
- All are application specific measures.
- System must achieve 100 mps throughput
 BAD!!
- System must achieve 100 mps peak throughput for PaymentReceived messages
 - GOOD!!!

Scalability

- "How well a solution to some problem will work when the size of the problem increases."
- 4 common scalability issues in IT systems:
 - Request load
 - Connections
 - Data size
 - Deployments

Scalability – Add more hardware ...

Scalability - reality

- Adding more hard ware should improve performance:
 - scalability must be achieved without modifications to application architecture
- Reality as always is different!
- Applications will exhibit a decrease in throughput and a subsequent exponential increase in response time.
 - increased load causes increased contention for resources such as CPU, network and memory
 - each request consumes some additional resource (buffer space, locks, and so on) in the application, and eventually these are exhausted
 - Data almost never completely independent

Message Brokers

- Developed specifically for Enterprise Application Integration (EAI)
- Add new layers of functionality to MOM
 - Message transformation
 - Rules engine
 - Intelligent routing
 - Adapters
- Typically (but not necessarily) built on top of a MOM layer

Message Broker Features

- Message transformation transform between different source/target formats
 - Graphical message format definition and mapping tools
 - High performance transformation engines
 - Message format repositories
- Intelligent routing
 - Route messages based on message content
- **Rules Engine**
 - Scripting language, built-in functions
 - Application programming environment

Message Brokers

Hub and Spoke Architecture

Output Messages

Adapters

- An adapter is a component that resides between the message broker and the source/target systems
- Simplify complexity of end system interface through an abstraction layer
- Thin adapters simple wrappers
- Thick adapters
 - Programmable
 - Abstract representation of services and meta-data
- Centralized adapters co-located with broker
- Distributed adapters execute in own process and may be located with source/target system

Business Process Orchestration

- Commonly known as workflow
- Aim is to automate business processes which need to access data and business logic across disparate back-end applications
- Builds on EAI to ensure business processes are executed in the defined order using the required data
- Builds on middleware providing:
 - Process execution engine
 - Visual process definition tools
 - Process monitoring tools

Typical Scenario

Business process automation

Message Broker

BPEL

- Web Services standard for describing workflows
- Many design and execution tools
 - Eg ActiveBPEL
- Version 2.0 is a significant improvement
