Outline

- 1. Dynamics of the benchmark model
- 2. Calibration
- 3. Volatility in alternative structures
- 4. Nonlinear dynamics in the labor market

(ロ)、(型)、(E)、(E)、 E) の(の)

DYNAMICS OF THE BENCHMARK MODEL

- Let x_t be the time-varying stochastic value of productivity.
- ► Use x̂_t ≡ (x_t x)/x as the proportional deviations of x_t around its deterministic steady state
- ► Similarly, use $\hat{\theta}_t$ as proportional deviations of labor market tightness.

- Assumptions
 - ▶ 1. Wage is fixed at some level \overline{w} within the bargaining set
 - ▶ 2. Elasticity of the matching function $\eta_L(\theta)$ is a constant η_L

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Using equation 1.19, the log-linearization around the steady state of the job creation condition with a fixed wage is:

$$\hat{\theta_t} = (\frac{1}{\eta_L})(\frac{x}{x-\overline{w}})(\frac{r+s}{1+r})\mathbb{E}_t[\sum_{i=0}(\frac{1-s}{1+r})^i\hat{x_t} + 1 + i] \qquad (1)$$

・ロト・日本・モート モー うへぐ

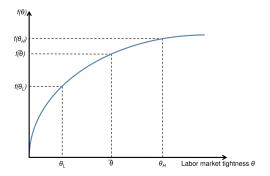

- First element of equation 2.1: The response of equilibrium labor market tightness to changes in labor productivity is decreasing in the elasticity of the matching function with respect to unemployment
- ► Second element: The response of market tightness is decreasing in the magnitude of the profit flow x w
- Amplification of labor market tightness due ti labor market congestion and the size of profit flow:

$$\frac{1}{\eta_L} \frac{x}{x - \overline{w}} \tag{2}$$

Asymmetries in the cycle

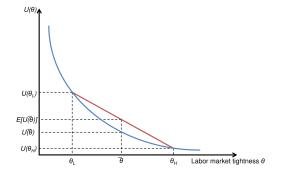

- Movements in labor market tightness affect the unemployment rate through the job finding rate f(θ_t
- The concavity of the matching function means that increases in unemployment during recessions will be pronounced
- Declines in unemployment during expansions will be modest

The Job Finding Rate as a Function of Labor Market Tightness

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへぐ

Relation of Market Tightness to Unemployment

◆□▶ ◆□▶ ◆注▶ ◆注▶ 注目 のへ(?)

Asymmetries in the cycle

- As economy fluctuates between high and low unemployment, the average rate of unemployment is strictly greater than steady-state unemployment
- The convexity of unemployment-labor market tightness is due to the congestion in the matching function
- The job finding rate decreases more as θ drops from its steady state to θ_L than it increases when θ rises to θ_H

CALIBRATION

▲□▶ ▲圖▶ ▲圖▶ ▲圖▶ = ● ● ●

Calibrated Parameters

Assumption: Use the model's stimulated moments, matching them to empirical moments in the calibration process

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Parameter Values in the Monthly US Calibration of the Benchmark Model

	Parameter	Value		eference or Target:		
Technology:						
persistence parameter	ρ_{x}	$0.95^{1/3}$	\rightarrow	BLS labor productivity		
standard deviation	σ_x	0.00625	\rightarrow	BLS labor productivity		
Labor market:						
job separation rate	5	0.035	\rightarrow	JOLTS		
matching curvature	ν_L	1.25	\rightarrow	DenHannRameyWatsonAER2000		
vacancy cost	γ	0.26	\rightarrow	Unemployment rate		
worker bargaining weight	α_L	0.50	\rightarrow	Equal surplus sharing		
nonemploymentnon-employment value	Ζ	0.71	\rightarrow	HallMilgrom2008		

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Discounting and Productivity

- The time discounted rate r is set to 4% per annum, which is the average return on 3-month US Treasury Bill.
- Labor productivity x assumed to follow AR(1) process in logs:

$$\log x_t = \rho_x \log x_{t-1} + \sigma_x \epsilon_t \tag{3}$$

$$\rho_x \in (0,1)$$

$$\sigma_x > 0$$

Matching Function Parameters

- Matching function $\mathcal{M}_L = \mathcal{V}_t \mathcal{U}_t / (\mathcal{V}_t^{\nu_L} + \mathcal{U}_t^{\nu_L})^{1/\nu_L}$, where $\nu_L > 0$, and set $\nu_L = 1.25$ (den Haan et al, 2000)
- Meeting rates $f(\theta_t)$ and $q(\theta_t)$ are bounded between 0 and 1

Flow Value of Unemployment z

- The value of z involves two components:
 - 1. a value of leisure and nonmarket activities I
 - 2. the value of unemployment benefits b
- Allowing for a leisure component *I* in the flow value of unemployment *z* permits a calibration of *z* above the replacement value of unemployment benefits.

Job Separation rate s

 Job separation rate (s) set to 3.5%, based on the Bureau of Labor Statistic's Job Openings and Labor Turnover Survey (JOLTS).

(ロ)、(型)、(E)、(E)、 E) のQの

Vacancy Costs γ

 γ is set such that the mean rate of unemployment in the model corresponds to the empirical sample mean of 5.80 percent.

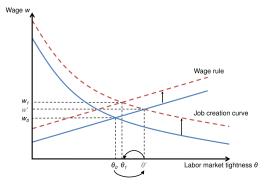

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

▶ γ = 0.26

Bargaining Weight α_L

- The Nash bargaining weight affects the importance of the time-varying components x_t and θ_t in the wage.
- A low value of α_L places most weight on the time-invariant flow value of unemployment z and the equilibrium wage fluctuates little over the business cycle.
- A high value of α_L allows productivity x_t and labor market tightness θ_t to make the wage pro-cyclical
- $\blacktriangleright \ \alpha_L = 0.5$; by using a symmetric sharing parametrization in the benchmark model

The Business Cycle in the Calibrated Model

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

The Business Cycle in the Calibrated Model

- Increase in productivity shifts job creation curve upwards
- Greater entry in labor market by firms
- Upward movement along the Nash wage curve from θ_0 to θ'
- Simultaneous increase in wage curve in proportion α₁ of the change in productivity

- Rise in wages limits amount of entry by firms
- New equilibrium tightness θ_1 is below θ'

VOLATILITY IN ALTERNATIVE STRUCTURES

Small Labor Surplus

- Increase the flow value of unemployment z up to 0.85. Keep all other parameters identical.
- New volatility of the labor market tightness is now 0.1 (up from 0.05).
- Narrowing the gap between the flow value of nonmarket activities and market productivity causes even small changes in productivity to induce proportionally large changes in the surplus from hiring labor.
- This amplifies the effect of productivity shocks on θ_t over the business cycle by a factor of two

Credible Bargaining

- Leads to less volatile wages
- Wage becomes less responsive to current labor market tightness
- Additional parameters:
 - 1. the negotiation breakdown probability arphi= 0.1
 - 2. the cost of delaying to the firm $\zeta = 0.25$
 - 3. reduce the flow value of unemployment to 0.60 such that $\zeta+z=0.85$

Entry Costs and Amplification

- Assume a job creation cost structure with a fixed post-match creation cost C > 0 to be payed upon hiring a worker
- The resulting average cost of recruiting, γ/q(θ_t) + C, is now augmented with C
- Job creation condition with fixed entry costs:

$$\frac{\gamma}{q(\theta_t)} + C = \frac{1}{1+r} \mathbb{E}_t \left[x_{t+1} - w_{t+1} + (1-s) \left(\frac{\gamma}{q(\theta_{t+1})} + C \right) \right]$$
(4)

Entry Costs and Amplification

Under assumption of a fixed wage the log-linearization of the job creation condition with extra costs is:

$$\widehat{\theta}_{t} = \frac{1}{\eta_{L}} \times \frac{x}{x - \bar{w} - (r+s)C} \times \frac{r+s}{1+r} \mathbb{E}_{t} \left[\sum_{i=0}^{\infty} \left(\frac{1-s}{1+r} \right)^{i} \widehat{x}_{t+1+i} \right]$$
(5)

Amplification due to labor frictions with fixed wage and entry cost C:

$$\frac{1}{\eta_L} \frac{x}{x - \bar{w} - (r+s)C} \tag{6}$$

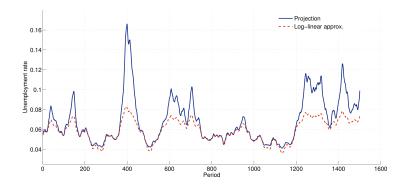

NONLINEAR DYNAMICS IN THE LABOR MARKET

Solving Models with Search Frictions

In order to determine the inaccuracy from log-linearization around a deterministic steady state for a search and matching model, solve the same model in two different ways:

- 1. global (projection) method
- 2. local (log-linearization)
- Then subject both solutions to a same path of labor productivity

Example of Path of Unemployment

▲□ > ▲圖 > ▲ 臣 > ▲ 臣 > → 臣 = ∽ 9 Q (?)

Example of Path of Unemployment

- The solid line represents the accurate global model
- Takes into account the curvature of the matching function for the evolution of unemployment as labor market tightness changes over time

Log-linearization model fails during recessions

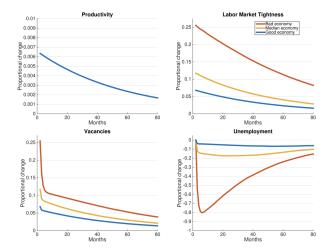

Labor market moments - the inaccuracy of local approximations

	Log-linear approximation					Global solution method				
	U	V	θ	x	_	U	V	θ	x	
Standard deviation	0.108	0.115	0.291	0.013		0.291	0.158	0.216	0.013	
Correlation matrix		-0.861	-0.818 0.817	-0.934 0.986			-0.496	-0.542 0.841	-0.593 0.873	
				0.842	θ				0.992	

Labor market moments - the inaccuracy of local approximations

- The first set of columns follow a calibration in the assumption of increasing the value of nonemployment z and it is a log-linearization approximation that is solved.
- The second set of columns uses a global method
- The volatility of unemployment is 3 times greater in panel B than in panel A
- the correlation between unemployment and vacancies is nearly halved

Impulse Response Functions

◆□> ◆□> ◆目> ◆目> ◆目 ● のへで

- Consider a shock during a midpoint of a business cycle when unemployment is at its median
- The strongest increase in labor market tightness θ_t is contemporaneous to the shock, returning to trend at the same rate as labor productivity
- Job vacancies exhibit a pronounced decline following the initial jump, then a progressive return to trend
- The rise in market tightness pushes job creation above job destruction, and the unemployment rate declines
- Job vacancies at a given level of labor productivity are increasing in unemployment
- During the first several months following the productivity shock, job vacancies are also responding to the sharp decline in unemployment
- In the subsequent months unemployment and job vacancies follow a similar paths back towards their trends

Impulse Response Functions

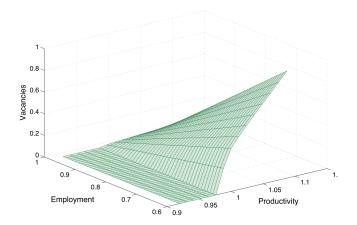

- Job vacancies and unemployment are complementary in producing new meetings per unit of time
- The dynamics of the labor market are more sensitive to shocks when the labor market is slack than when it is tight

Other nonlinearities: the small surplus assumption and the zero bound for vacancies

- Firms enter the labor market posting job vacancies as long as the expected benefit from filling the job exceeds the cost of posting a vacancy.
- If the cost γ is greater than E_t[J_{πt+1}], then there is no surplus to entering and the result is a shutting down of hiring with V_t = 0.

Job Vacancies in (x, \mathcal{N}) space

▲ロト ▲園ト ▲ヨト ▲ヨト ニヨー のへ(で)

Model Job Vacancies Time Series

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 = のへで

Model Job Vacancies Time Series

- First 50 periods are standard response of model to stochastic change sin productivity
- Series of negative shocks pushes productivity under its boundaries
- Corner solution $V_t = 0$ for several periods
- Existing jobs continue to be destroyed at rate s and there is a sharp rise in unemployment
- When productivity finally returns to a value such that firms enter the labor market once again, employment is very low and there is massive entry by firms into the market.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <
